ABSTRACT

**Introduction:** Application of microwave irradiation is a relatively new development in materials processing. Recent development of microwave digestion for extremely acidic conditions like high temperatures – pressures gives more rapid, efficient and precise digestion. **Methodology:** This study optimizes the temperature and time, for dissolution of silica under acidic condition using microwave irradiation. The etched silica can be utilized for the synthesis of new species of aluminosilicates through various techniques like precipitation/evaporation. **Result and Discussion:** In our study, we have synthesized fly ash zeolite by using the microwave acid digestion method. This calls for utilization of industrial byproduct-fly ash in zeolite synthesis using silica reduction technology.

**Keywords:** Synthesis, Zeolite, Silica Reduction Technology (SRT), Etching

**INTRODUCTION**

In the last decade, the use of microwave digestion became increasingly popular. The use of closed vessel microwave assisted digestion system under high temperature and pressure has now become practical. Compared to traditional method, this procedure promotes the nucleation and crystal growth, allows shorter digestion time, gives homogeneous heating throughout the reaction vessel, activation time needed can be drastically reduced (from 24-48 h to 30 m) and good recoveries. Furthermore, it requires a small amount of acids, reduces risks of external contamination, improved detection limits and improved overall accuracy. Studies have shown that the use of a microwave is easy, rapid, efficient, robust, reliable and cheap method.

Microwave can transfer energy directly to the reactive species, so-called “molecular heating” and promote transformations that are currently not possible using conventional heat. Energy is applied directly to the reactants; however the bulk heating is reduced by use of simultaneous cooling. This allows for enhanced reactions of larger, more heat sensitive molecules, as the temperatures are low enough to eliminate thermal degradation. The key features of this device shall be mainly useful for the synthesis of zeolites: short digestion time, no loss of volatile elements, no acid fumes, no sample contamination, no cross contamination, operation is unattended, minimum quantity of acid (mainly hydrofluoric acid (HF)) is required, complete documentation including reaction kinetics, closed vessel technology. This instrument is used to digest small amounts of material for chemical analysis by placing the sample in a Teflon crucible adding acid and microwaving the sample for a certain amount of time.
Microwave digestion inherited some disadvantages; most of these problems are associated with the usage of HF. It has been found that for digestion of silica, addition of HF proved to be necessary. In order to insure the maximum digestion of silica from fly ash, it has been opined by the previous researchers that the microwave can be employed for complete heating of fly ash samples as compared to the conventional hydrothermal method. Based on this, the main objectives (viz., less activation and digestion time, maximum silica digestion, more nucleation and better crystal growth of zeolites) of the present work have been planned. The aim of this study is to try to understand key parameters – temperature, effect of HF; based on that modify and further improve microwave digestion method for optimum silica reduction.

1. Experimental

MATERIAL
In the early alkali aluminosilicate synthesis of the low silica zeolites, it has been proposed that the hydrated alkali cation ‘templates’ stabilizes the formation of the zeolite structural units. Alkali hydroxide, reactive forms of alumina and silica, and H₂O are combined to form a gel. Crystallization of the gel to zeolite occurs at a temperature near 100°C. The reactive gel is heated to crystallize the molecular sieve product.

Fly ash samples from the Bhusaval Thermal Power Station (BTPS), Bhusaval, Maharashtra, India; were collected for the present study. The ash sampling was done from hoppers and representative samples were prepared for three fields by mixing the collected samples. The hydrofluoric acid was procured from Merck Ltd. and is used for fly ash dissolution and subsequently for synthesis of zeolite.

METHOD

Microwave digestion: The fly ash with 40% of HF (AR) is exposed to microwave irradiation for the acid digestion of the fly ash, in closed vessels, maintaining the liquid to solid ratio 10. The activation temperature is maintained from 45 to 110°C. The activation time given is 5 m. At the end of these activation periods, the deep brown colored mixture was obtained which was then filtered using watman filter paper no. 41 (5−A) and liquid was collected into propylene bottle. Filter paper was dried in hot air oven at 65°C for around 6-8 h. The solid dried residue was scraped and collected in polythene bag. The experimental set up consisting microwave digester is shown in Fig.-1 (a) and 1 (b):

![Fig.-1 (a): Schematic of Microwave Digester](image-url)
The digestion was performed in closed vessels (volume 100 ml). Reaction parameters are temperature, reaction time (5 min) and sample to reagent ratio (L/S = 10) kept constant (shown in Table-1 and 2). The heating cycle was based on the power settings from 400, 800 and 1600 Watt. Digestion pressure is atmospheric pressure. 1 g of fly ash was taken into the digestion vessels with 10 ml of HF. No stirring was provided. It is then allowed for around 15 min of natural digestion with HF. The initial temperature of digester was maintained at 37 °C. After the final temperature is achieved, microwave digester was kept at that temperature as per the set program and heating duration of 5 min. Finally, after the completion of microwave process, the digesting vessels were allowed to cool within the digester only. All the vessels were taken out of the digester. Safety precautions should be taken while opening the vessels. A relaxation time of 5-10 minutes was allowed for the mixture. The mixture was later transferred to a filtration unit for the separation of solid residue and the liquid supernatant. The resultant liquid was collected into the propylene bottles and kept for further analysis. In order to separate out the solid residue from the filter paper, the filter paper was kept in the hot air oven at around 65 °C for about 12 h for complete drying. All the solid particles left over on the surface of the filter paper, were scraped and stored in polythene bags for further analysis.

Characterization

Determination of dissolved silica

The solution obtained after separation of activated fly ash residue, was subjected to elemental analysis for the determination of silica content. The results obtained are presented in Table-4 and 5.

Complete elemental analysis of fly ash was carried out using inductively coupled plasma - atomic emission spectrometer (ICP-AES). Model: ARCOS from M/s. Spectro, Germany. The excited electrons emit energy at a given wavelength as they return to ground state after excitation by high temperature argon plasma. The fundamental characteristic of this process is that each element emits energy at specific wavelengths peculiar to its atomic character. The energy transfer of electrons when they fall back to ground state is unique to each element as it depends upon the electronic configuration of the orbital. The energy transfer is inversely proportional to the wavelength of electromagnetic radiation, $E = \frac{hc}{\lambda}$ ... (Where $h$ is Planck’s constant, $c$ the velocity of light and $\lambda$ is wavelength), and hence the wavelength of light emitted is also unique. Although each element emits energy at multiple wavelengths, in the ICP-AES technique it is most common to select a single wavelength (or a very few) for a given element. The intensity of the energy emitted at the chosen wavelength is proportional to the amount (concentration) of that element in the sample being analyzed. Thus, by determining which wavelengths are emitted by a sample and by determining their intensities, the analyst can qualitatively and quantitatively find the elements from the given sample relative to a reference standard.

RESULTS AND DISCUSSION

Results of various tests conducted on the samples are being presented here. The results indicate that the temperature above 200 °C, does not have much effect on the silica dissolution. At lower temperature only, it can be possible to achieve the required amount of digestion of silica (shown in Table-3, Fig.-2). The effects of digestion with temperature change on samples are illustrated in Fig.-3 and Table-4. For most of the elements, observed temperature suggested by the original methods (60-65 °C) was found to be optimal. The recoveries for Si, Al, Fe and other trace elements were best when the sample was irradiated at 60-65 °C. Fig.-4 and -5 and Table-5 shows the effect of digestion with respect to time change on elemental recovery. Recovery of the elements remained unaffected in most of the cases; which in this case, too, seem to be optimized by the digestion time. Compared to the conventional digestion methods, microwave method consumes less time and increases efficiency in fly ash sample digestion. The expenses and costs need to be explored for pilot plant.
experimentation, with the available technology. It can be concluded that the establishment of an efficient, cost effective, fast route (from hours to minutes) and environment friendly way of the synthesis of fly ash zeolite gives good recoveries using fluoride-containing medium with microwave irradiation.

CONCLUSION

It is necessary to study the desired properties of synthesized zeolite. Different synthesis methods should be used or the zeolite must be modified, to meet the specifications. Zeolite synthesis, - modification, - characterization and - application thus are strongly related. A simplified description of the structure types, interrelationship between structural subunits, the effect of several parameters on the synthesis of fly ash zeolite through microwave digestion process; needs to be investigated further. The increasing requirements for the environmental protection have resulted in the search for more effective, inexpensive and ecologically safe solutions and zeolites are one of the alternatives, which due to their peculiar structure are widely used for various environmental processes. The demand for an easily accessible and inexpensive source of zeolites has raised interest in synthesis of these minerals. The extraction of natural zeolites from the deposits has certain disadvantages, like comparatively more expensive, causes degradation of the environment despite their better efficiencies. On the other hand the disposal and storage of fly ash as waste from the Thermal Power Plant’s is a large problem in the power generation industries. The dumped fly ash may be a significant resource for the production of the zeolite. Such secondary optimization of wastes supports activities aiming at lithosphere protection and is consistent with the guidelines for sustainable development. The non-biodegradability of these materials is a major disadvantage since landfill disposal is environmentally undesirable and incineration is very expensive. It is suggested that the use of zeolite may prove very economical, technically feasible and environmentally acceptable technology, particularly those prepared cheaply from fly ash, aluminum refining wastes and other solid waste materials containing silica and alumina may find application in many fields while simultaneously providing a solution to various environmental problems. The synthesizing capability of microwave from fly ash to zeolite has positive impacts on utilization of wastes coming from solid fuel combustion by converting the fly ash into valuable raw material and simultaneously accomplishing the lithosphere protection effect.

ACKNOWLEDGEMENT

The authors acknowledge the immense help received from the scholars whose articles are cited and included in references of this manuscript. The authors are also grateful to authors / editors / publishers of all those articles, journals and books from where the literature for this article has been reviewed and discussed.
